Abstract

Under IDEA 2004, a Pattern of Strengths and Weaknesses (PSW) model may be used in SLD identification. We discuss factors to consider when operationalizing a PSW model, and report a study comparing a PSW model and the ability-achievement discrepancy model applied to a mixed sample (with and without existing SLD classifications). The models agreed on 74% of cases, but showed some differences in the number and characteristics of the students identified.

The following are broad characteristics of several models.

Name of Model:	Consistency-Discrepancy	Concordance-Discordance	Aptitude-Achievement Consistency	Dyslexia	Oral & Written Language LD
Authors:	Naglieri (1999)	Hale & Fiorello (2004)	Flanagan, Ortiz, & Alfonso (2006)	Berninger (2007)	Berninger (2007)
Achievement weakness	---- consistent with related processing weakness < unrelated processing strength < achievement strength	<= 85 consistent with related processing weakness < unrelated cognitive strength	<= 85 consistent with related processing weakness < unrelated cognitive strength	< 100 15+ points below verbal ability	< 90 ----- ----- < achievement strength
Cognitive/process weakness (related to achievement weakness)	< child's average processing score consistent with achievement weakness	---- consistent with achievement weakness	<= 85 -----	< 90 -----	< 90 -----
Cognitive strength (unrelated to achievement weakness)	any PASS process ----- > unrelated achievement weakness > child's average processing score consistent with achievement strength	verbal ability, perceptual reasoning ----- > unrelated achievement weakness > cognitive/process weakness related to achievement weakness	ability, not process > 85 (see EXBA-2 for further criteria)	verbal ability verbal ability >= 90 -----	perceptual reasoning percept reas >= 80 ----- -----

Conversations when Evaluating PSW Models

Measures used to demonstrate "normal" cognitive functioning.

- Some cognitive measures are affected by processing deficits related to SLD, making them inappropriate as criteria for normal cognitive functioning.
- Variability among broad cognitive abilities is common in the population.
- A broad ability/process with a low g loading may be the only average or high score in a profile of otherwise low ability scores, but would not be a good indicator of normal cognitive functioning.

Thus, a PSW model cannot require every broad cognitive ability measure to be average or above. However, a PSW model tailored to a particular SLD (e.g., Berninger) may specify the broad ability that must be average or above.

Criteria for "normal" cognitive functioning.

- Flanagan/Ortiz/Alfonso, Berninger (Dyslexia): average or above (>85 for Flanagan; VCI >=90 for Berninger)
- Berninger (OWL LD): PRI >= 80
- Hale/Fiorello, Naglieri: no normative criterion; significantly higher than the cognitive-processing weakness that is related to the achievement weakness

How low must the achievement deficit be?

- Flanagan, Hale/Fiorello: low (standard score below 85)
- Berninger: for dyslexia, below the median (<100); for OWL LD, low (<90)
- Naglieri: no numerical criterion

What demonstrates a deficit in a process related to the achievement deficit? (Note that all models require the process to have a research-based theoretical relationship to the achievement deficit.)

- Berninger: normatively low (<90)
- Flanagan/Ortiz/Alfonso: normatively low (<= 85), significantly lower than the cognitive strength, and not significantly higher than the achievement deficit
- Hale/Fiorello, Naglieri: significantly lower than the cognitive strength, and not significantly higher than the achievement deficit

Comment: In practice, the Berninger and Hale/Fiorello criteria are similar, although the former is more stringent; assuming reliabilities of .9 for the achievement and process scores, the process score in the Hale/Fiorello model can be no higher than 94.

Application of a PSW Model to a Sample

Sample

1,036 students aged 6 to 19 who were included in either the 2003 WIAT-II®/WISC-IV® validity study or the 2008 WIAT-III® special-group studies; 24% had a school-designated SLD classification (14% in Reading/Writing, 4% in Reading/Writing/Math, and 6% in Math).

Operational criteria applied in this analysis

- WISC-IV Indexes used as measures of cognitive processing
- Both methods require an achievement standard score <=85 in the area of SLD classification
- .05 significance level used throughout.

AAD (Regression Method)

- Actual achievement significantly lower than FSIQ-predicted achievement.

PSW

- Processing strength: Higher of VCI or PRI
- Processing weakness: Lowest Index score (regardless of clinical classification)
- Processing weakness significantly lower than processing strength (simple difference)
- Achievement weakness significantly lower than processing strength (simple difference)

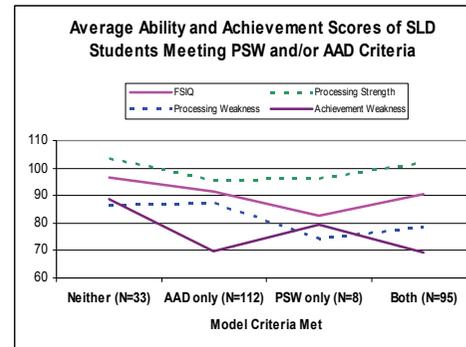

Results

- Of the entire sample (including 24% with existing SLD classifications), 47% met AAD criteria and 25% met PSW criteria; 23% met both.
- 91% of those meeting PSW criteria also met AAD criteria.
- Total agreement: 74% (vs. 52% expected by chance); Cohen's Kappa = .46 (moderate agreement)

Comparison of Four Subgroups

Among the 248 students with an existing SLD classification, there were significant ($p < .05$) differences between the PSW Only, AAD Only, Both, and Neither subgroups in both ability and achievement:

- FSIQ was higher in the Neither group than in the PSW Only and Both groups.
- Achievement was higher in the Neither group than in all other groups, and was higher in the PSW Only group than in the AAD Only and Both groups.
- Processing weakness was lower in the PSW Only and Both groups than in the AAD Only and Neither groups.

Study Limitations

- In practice, the proportion of students identified by practitioners as having an SLD will vary from the proportions reported here for the following reasons:
 - Students are not identified as having an SLD solely based upon score patterns, but following a comprehensive evaluation that incorporates multiple sources of information.
 - In this study, the processing strengths and weaknesses were selected without consideration of their theoretical relationships to the achievement weakness.
 - It is likely that most of the prior SLD classifications were based on an AAD criterion.
